Broad definitions –An introduction to understanding the terminology

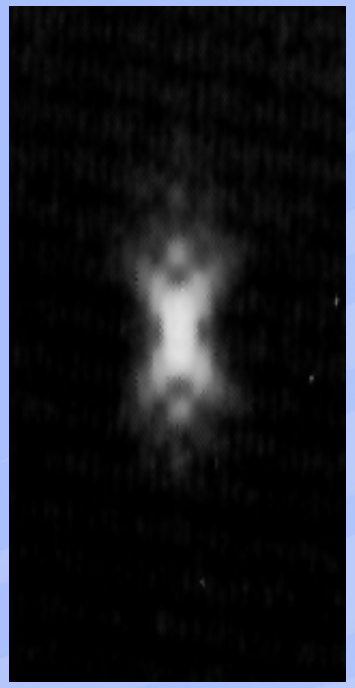
1. Define optical section in terms of the mathematics:
   - Lateral resolution: for diffraction limited techniques: where d is the smallest resolvable unit, λ is the wavelength of light, and NA is the numerical Aperture of the objective lens.

$$d_{xy} = \frac{1.22\lambda}{(2NA)}$$

Example: For a 1.4NA objective at 550nm, the resolution limit is 240nm.

Broad definitions –An introduction to understanding the terminology

1. Define optical section in terms of the mathematics:



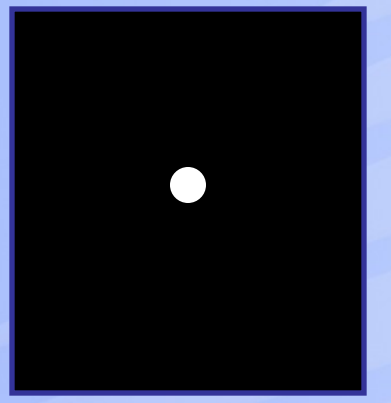
- Axial resolution (focal volume): Again, for diffraction limited techniques, the axial resolution is given as: where η is the refractive index of the media.

$$d_z = \frac{2\lambda \cdot \eta}{(NA_{obj})^2}$$

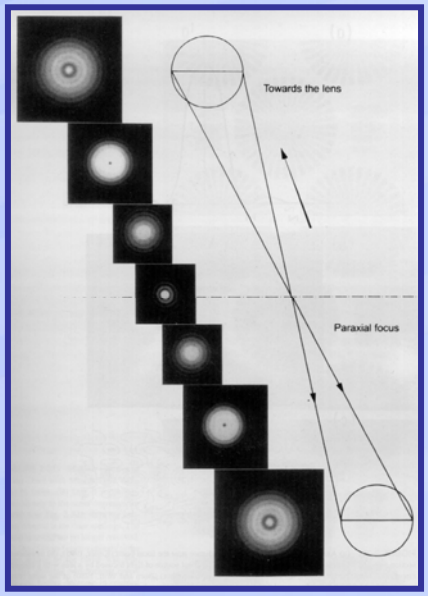
Example: For a 1.4NA objective in oil/oil, at 550nm, the resolution limit is 850nm.

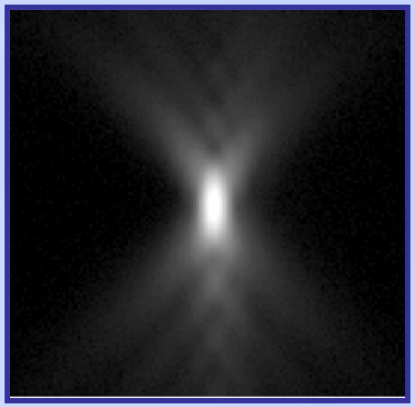
Point Spread Function

- **PSF defines the propagation of electromagnetic radiation or other imaging light rays from a point source or point object.**
- **The degree of spreading of the point object is a measure of the imaging system.**
- **The effect of the imaging system on a point object is termed the convolution of the optical system.**
- **Displayed by imaging a sub micron point in 3D (Z stack) and displaying as a volumetric airy disc. (X-Z projection)**



Diffraction limited Point Source



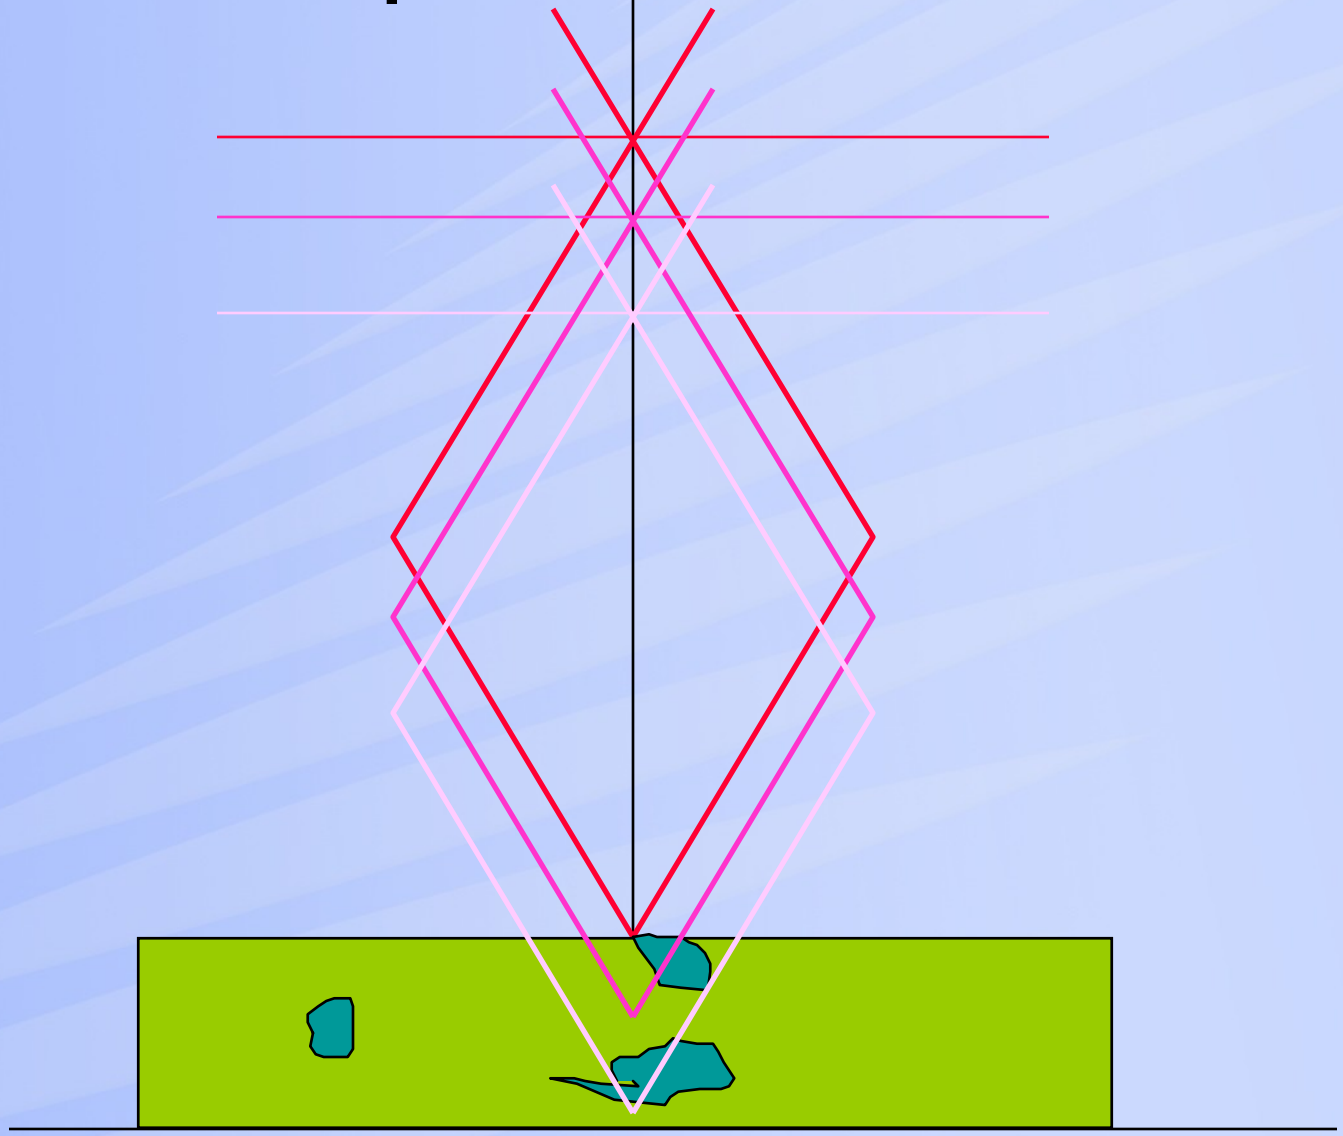


Optical Convolution of Point Source

The Eyes of Science

Nikon

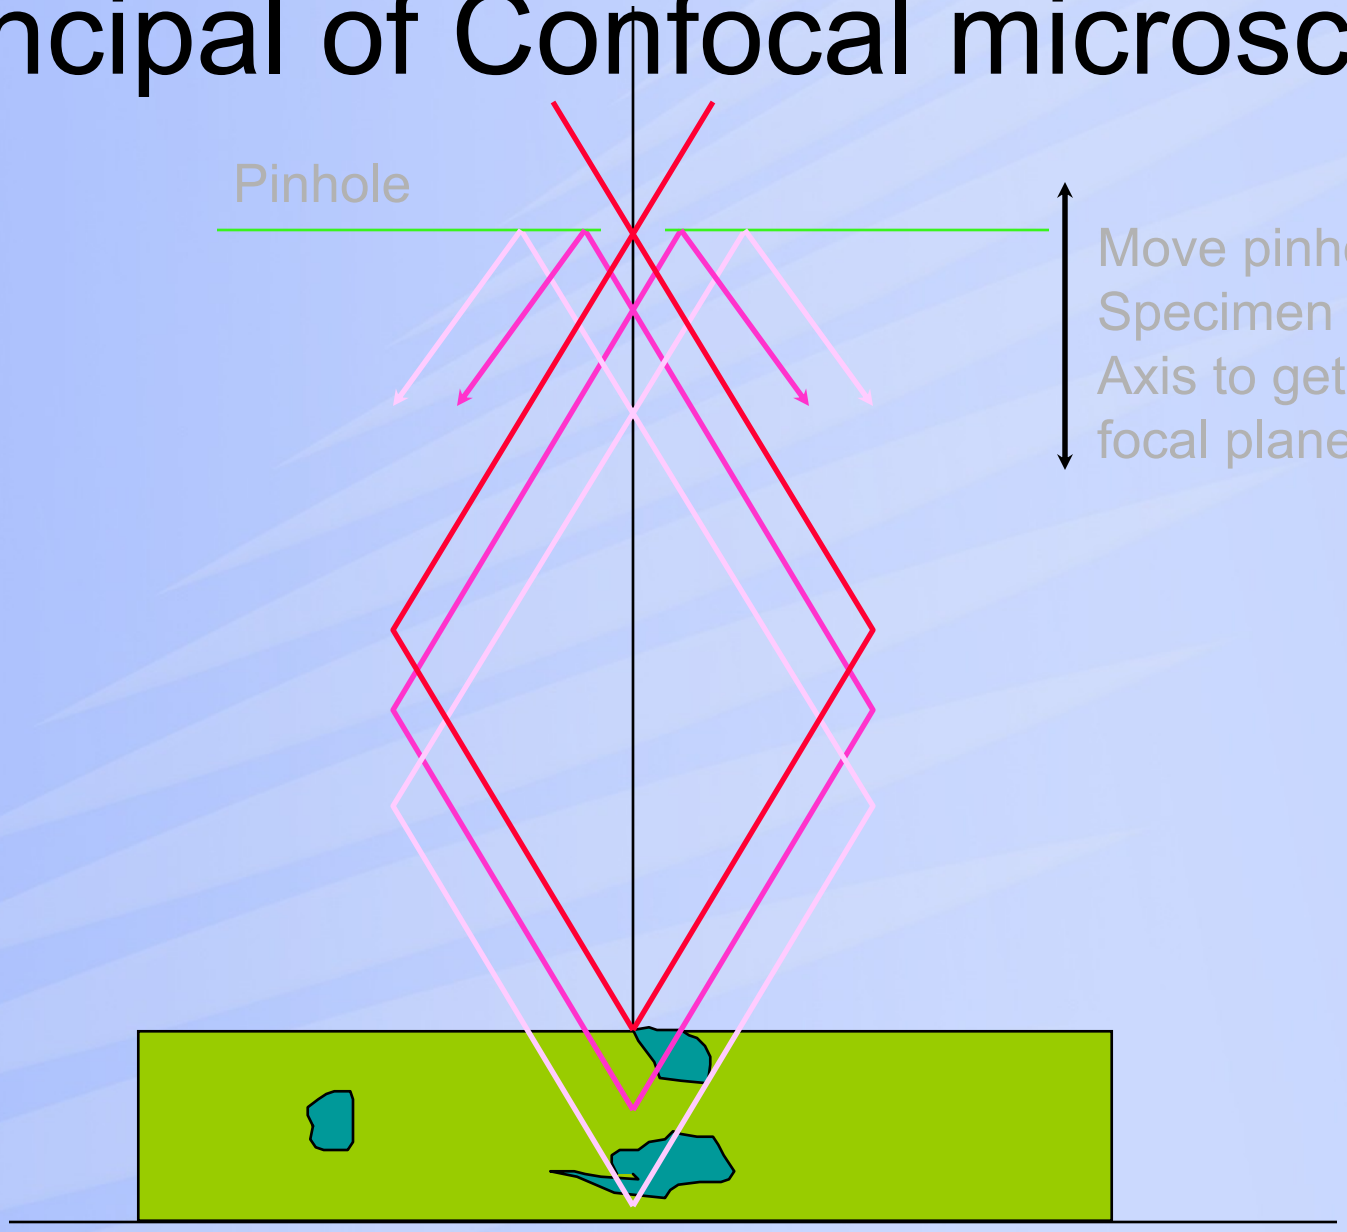
Multiple Focal Planes



Conventional light microscopy is limited by multiple focal planes in the same section, therefore:

- Physically cut thinner sections
  - Technically difficult
  - Highest resolution
  - Highest sensitivity
- Optical sectioning using confocal microscopy
  - Technically simple
  - Multiple section planes available
  - Complex computing

Principal of Confocal microscopy



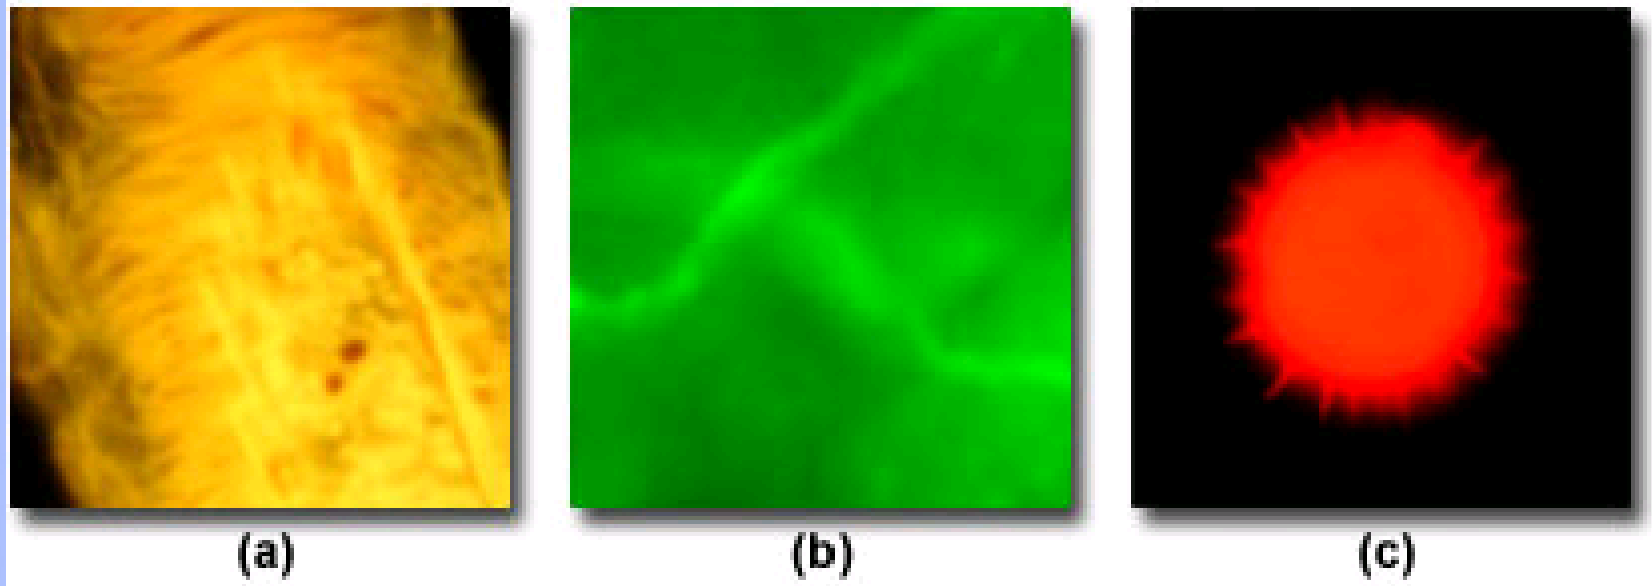
The Eyes of Science

Nikon

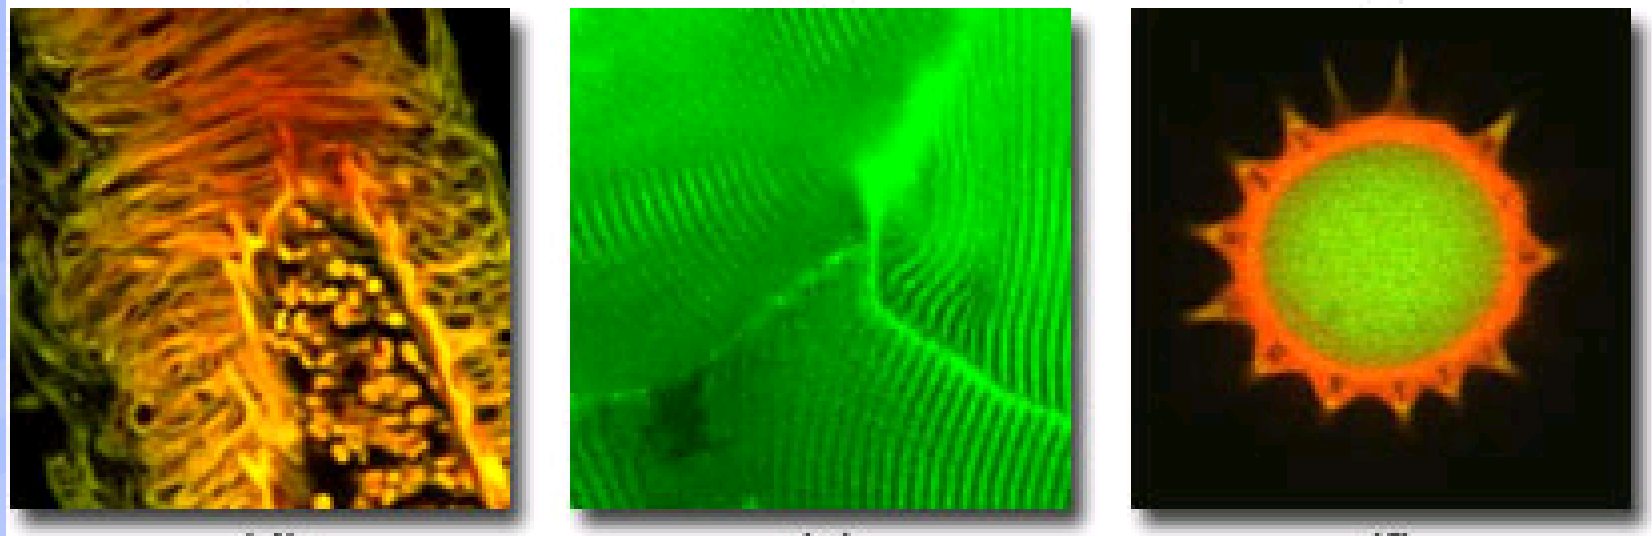
Pinhole size and resolution

- Pinhole size should be related to width of point spread function
- Width of point spread function = resolution of lens × magnification of lens = 1 Airy unit
  - 100x / 1.4 NA: resolution = 220nm, so 1 Airy unit = 22 μm
  - 40x / 1.3 NA: resolution = 235nm, so 1 Airy unit = 9.4 μm
  - 20x / 0.75 NA: resolution = 407nm, so 1 Airy unit = 8.1 μm
  - 10x / 0.45 NA: resolution = 678nm, so 1 Airy unit = 6.8 μm

Confocal and Widefield Fluorescence Microscopy

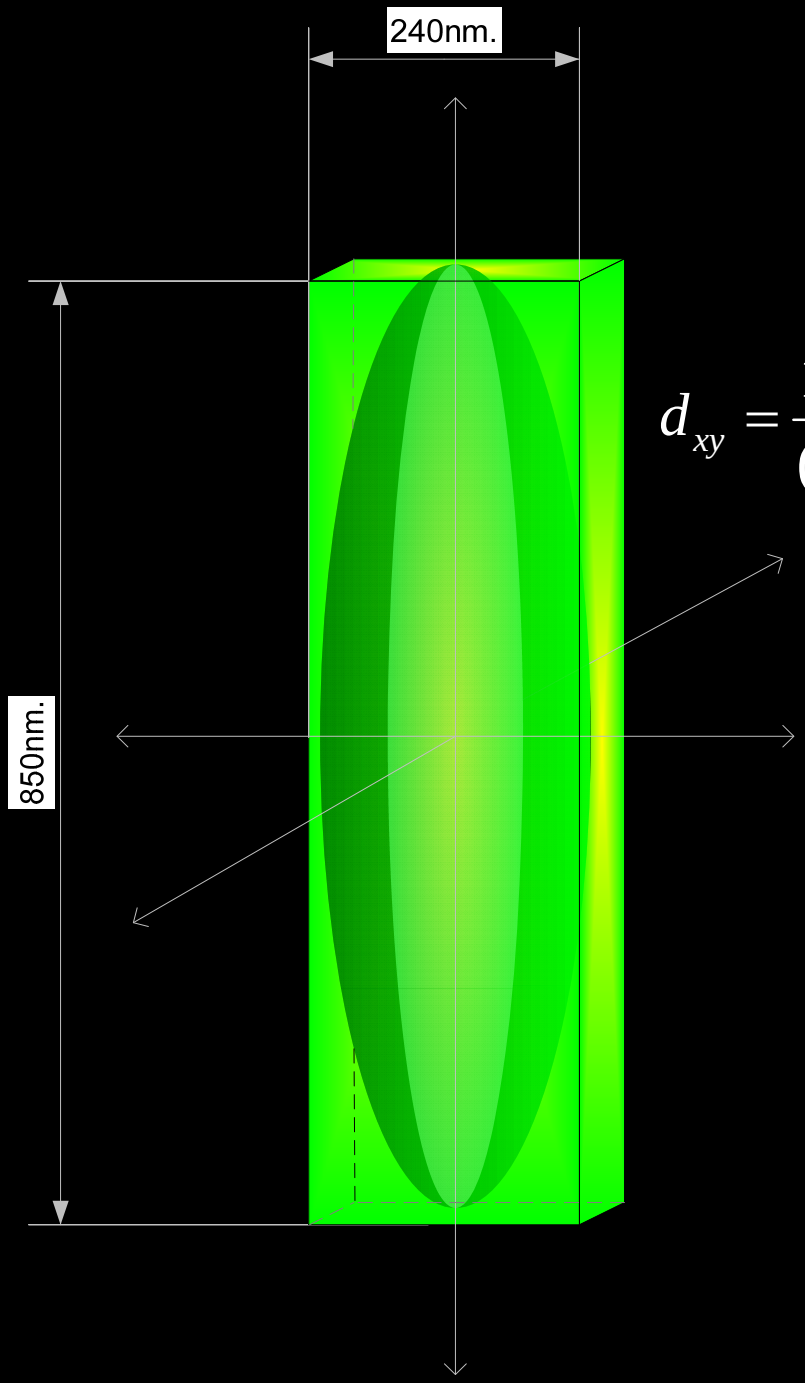


(a) (b) (c)



(d) (e) (f)

Figure 1



Diffraction limited volume :

NA = 1.4

η (Refractive Index) = 1.515

λ (Wavelength) = 550 nm

$$d_{xy} = \frac{1.22\lambda}{(2NA)} = \frac{1.22 \cdot 0.55\ \mu m}{(2 \cdot 1.4)} = 0.24\ \mu m = 240\ nm$$

$$d_z = \frac{2\lambda \cdot \eta}{(NA_{obj})^2}$$

$$= \frac{2 \cdot (0.55\ \mu m) \cdot 1.515}{(1.4)^2} = 0.85\ \mu m = 850\ nm$$

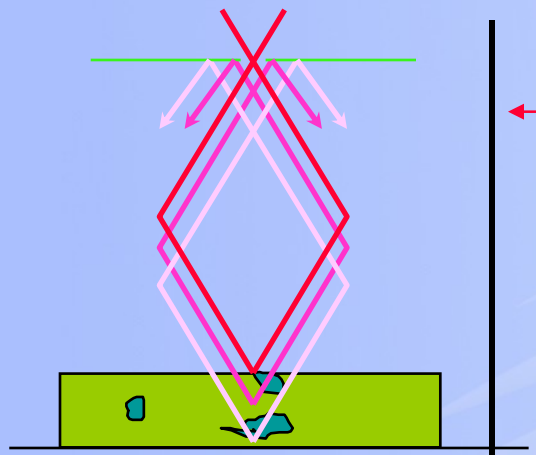
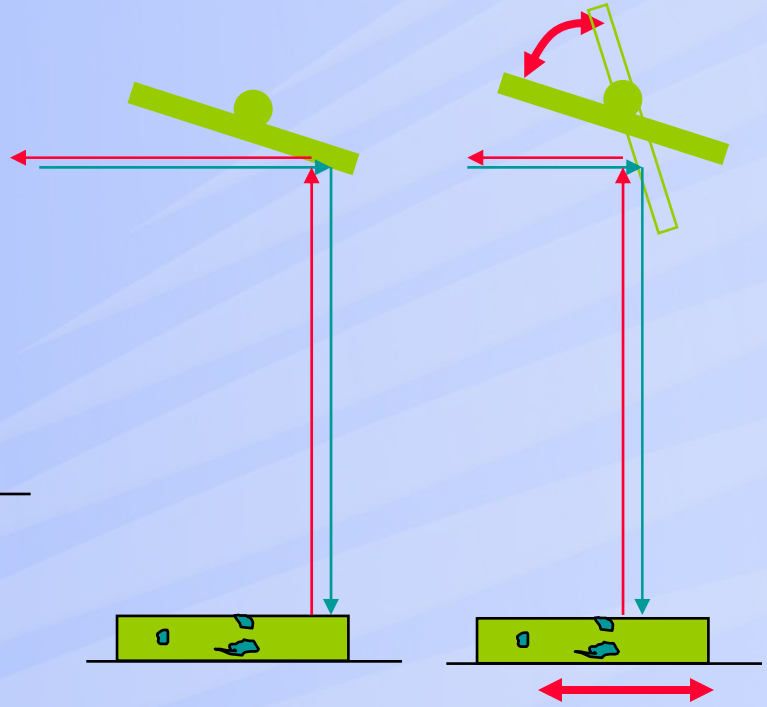
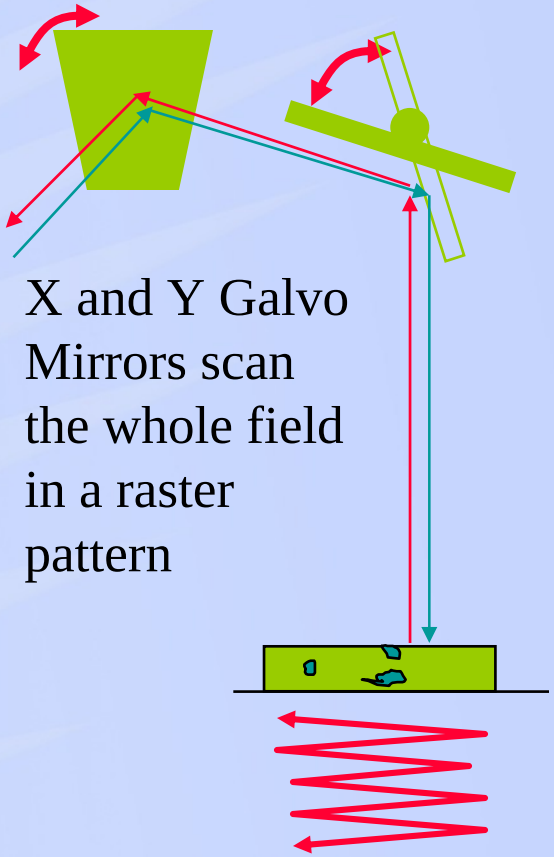
How a Point Scanner Works



The pinhole will only provide information about a single point in space. Therefore move specimen or move the exciting light





X and Y Galvo Mirrors scan the whole field in a raster pattern

- Note that the mirrors also descan the returning light
- Many systems have been developed to control the scan mirrors
- Also motorize Z-axis to sample points in vertical axis

The Eyes of Science

Nikon

Commonly used Lasers

• Argon	Ar	457, 488, 514 nm
• Krypton-Ar	Kr-Ar	488, 568, 647 nm
• Helium-Neon	He-Ne	lots single line sources 543, 594, 633 nm
• He-Cadmium	He-Cd	325 - 441 nm
• Diodes	350, 405, 442, 473, 488, 491,514, 532, 561,593, 638, more coming!	

Photomultipliers (PMTs)

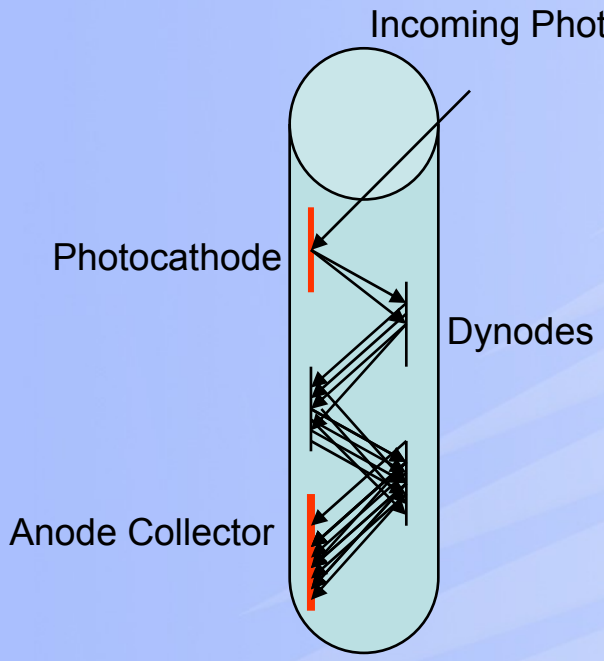


Photo Multiplier Tube

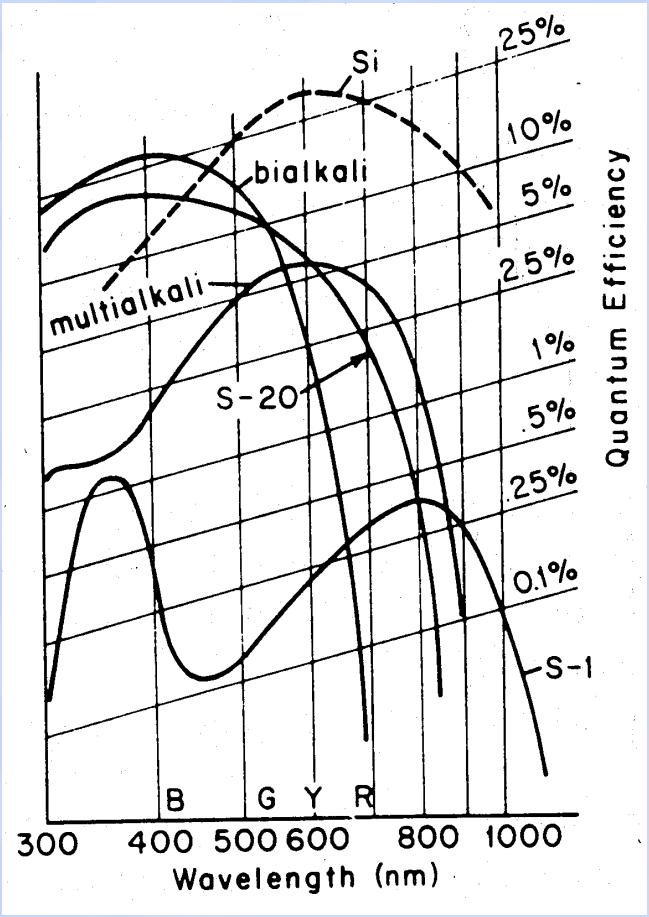
•Maximize the light budget returning from the scan head by intensification.

•Subject to electrical noise to much gain will degrade image and demand excessive averaging

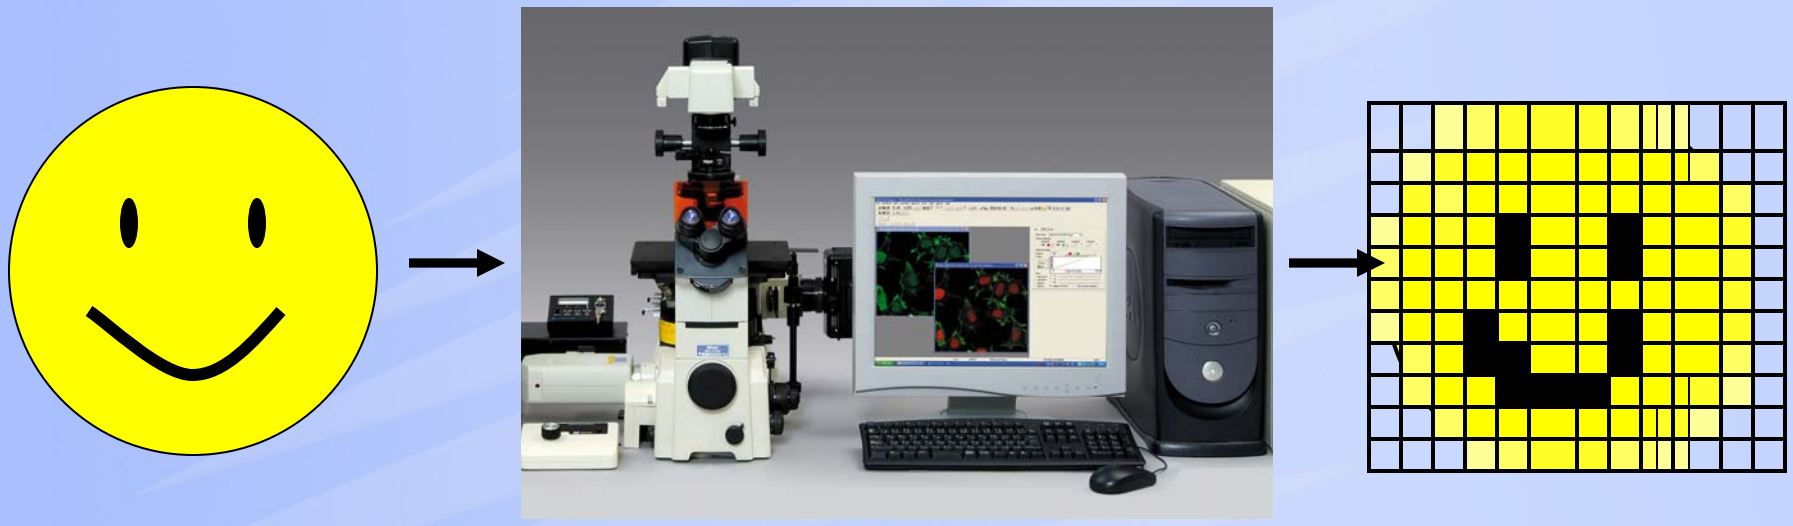


PMTs must be matched with detection wavelength

The Eyes of Science

Nikon

Computer builds digital image from scanned data



The Eyes of Science

Nikon

Due to PMT Noise, Averaging is commonly used to enhance S/N

SFC Design Overview

- Supravideo rate, high frequency slit scanner.
- Variable pinhole, linear array field scanner.
- CCD camera-based detector.
- Linear scanning at high frequency minimizes phototoxicity.

SFC Design Overview, cont'd.

- Variable pinhole sizes match various objective lenses.
- Linear pinhole array (1-D) and separate excitation and emission light path minimize emission crosstalk.

Galvo “Sweep”

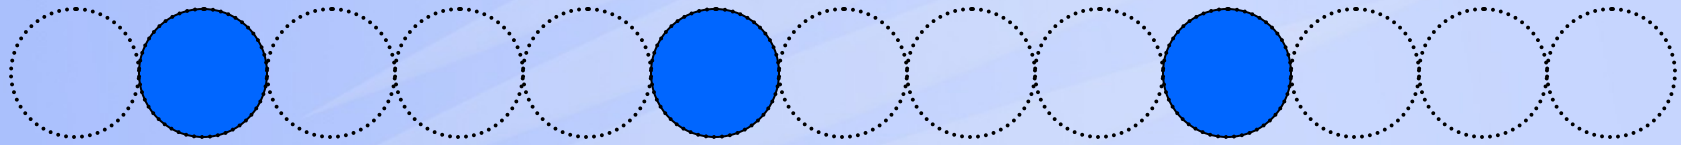
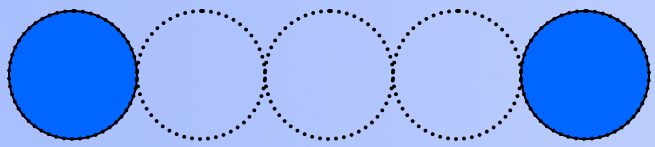
Piezo movement of Pinhole image

CCD Frame #1 (or odd #s)



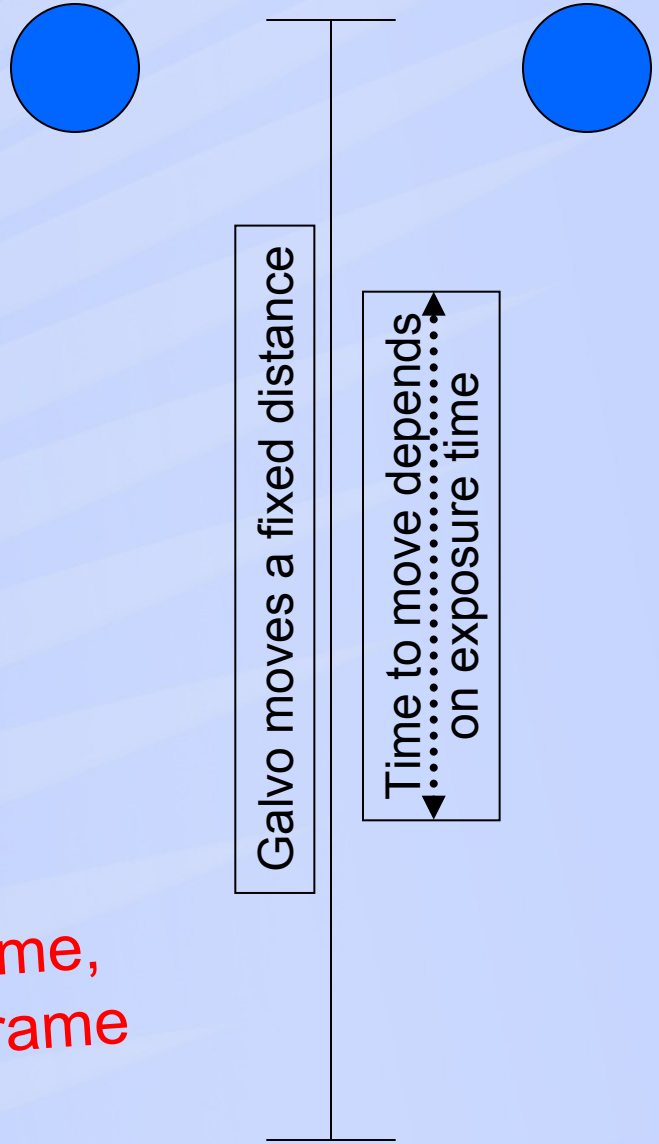
CCD Frame #2 (or even #s)



Piezos move a fixed distance

Time to move depends on exposure time

It takes 2 frames for one complete “piezo sweep”

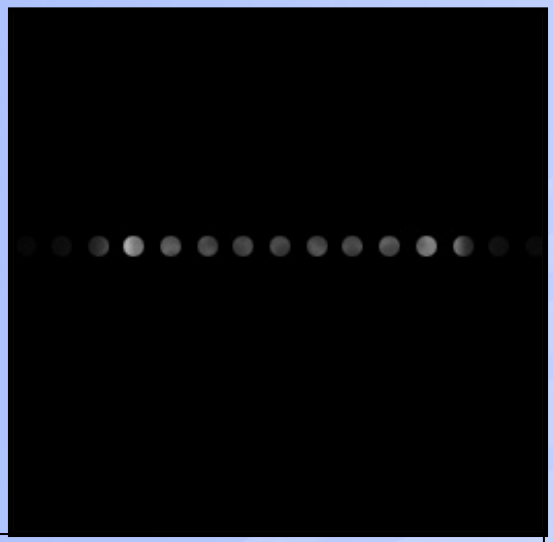


Galvo sweeps **multiple** cycles/frame, and piezos sweep only **once** per frame

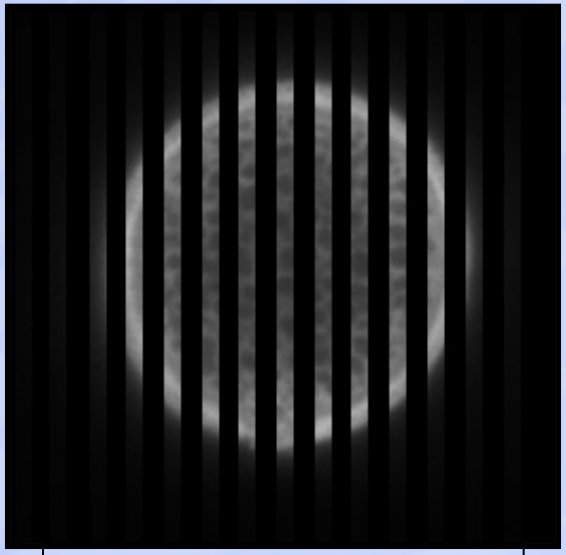
Galvo cycles multiple times / frame

Field-scanning combines multiple galvo sweeps
with bidirectional piezo movement

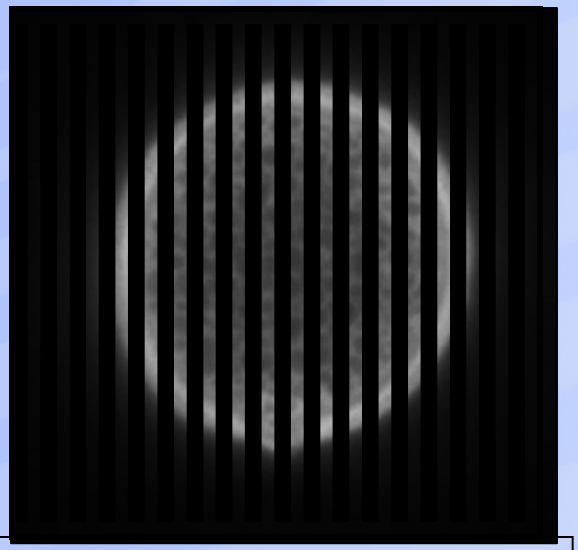
Piezo step
Galvo “Sweep”



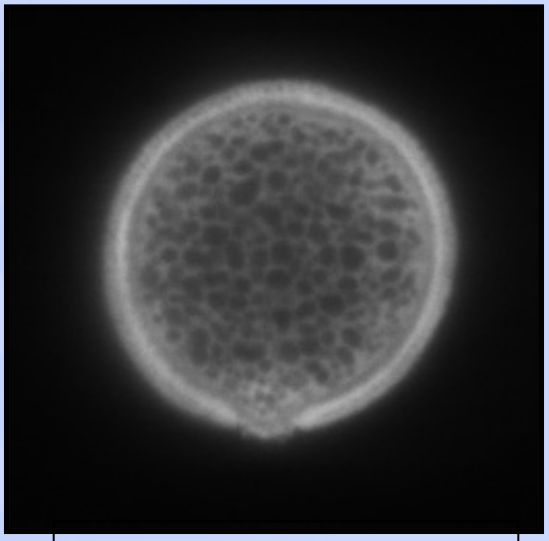
Galvo, Piezos stationary



Sweeping galvo only



Sweeping galvo & piezos



Piezo sweep synch with frame rate

Performance

- Slit scan imaging to 1000Hz with appropriate detector.
- Pinhole scan imaging to 100Hz.
- Axial resolution from ~ 0.4μm to 1.2μm over 6 scanning modes.

- **Total Internal Reflection Fluorescence (TIRF)**

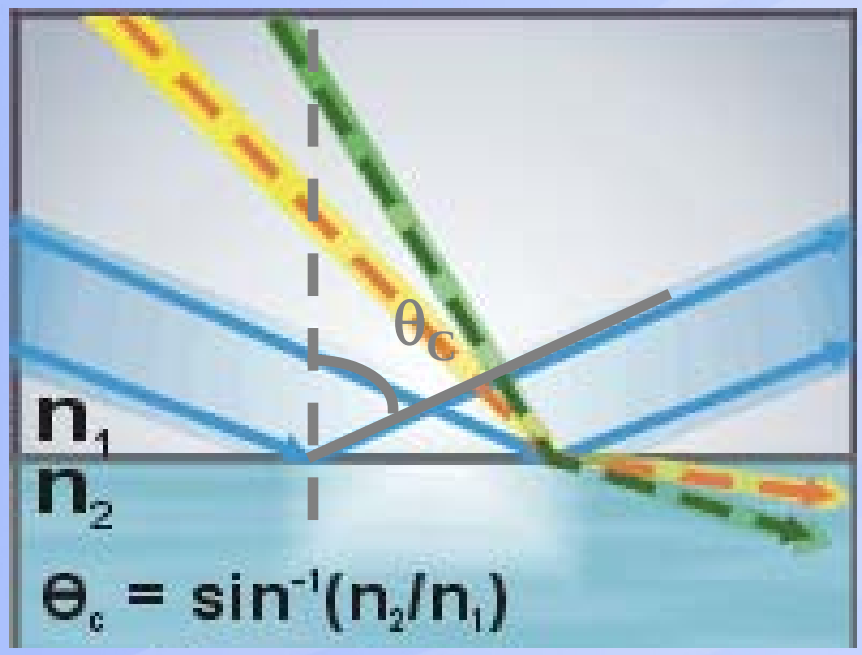
What is Evanescent Wave or Total Internal Reflection Fluorescence (TIRF) Microscopy?

- **An optical phenomenon that can occur when light strikes the interface between two media of different refractive indices**

- **When light is totally internally reflected it does not propagate through the sample, but causes an electromagnetic field (termed the evanescent wave) that extends in the z-direction**

- **The evanescent wave intensity decreases exponentially, and extends only a few hundred nanometers into the second media**

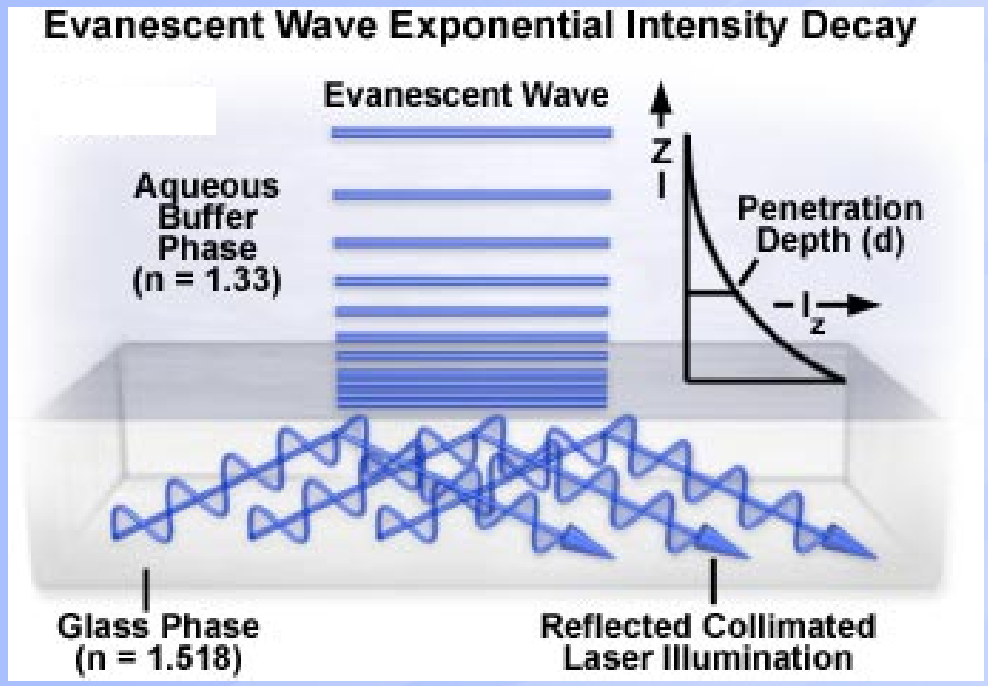
Glass (n=1.515)



Live cells (n=1.33-1.38)

Criterion for TIR

- $N_1 > N_2$
- **The angle of incidence must be ≥ the critical angle (θ_C)**



$$E_z = E_0 \exp(-z/d_p)$$

$$d_p = \frac{\lambda_i}{2\pi n_1 \sqrt{\sin^2\theta_i - (n_2/n_1)^2}}$$

- The energy of the evanescent wave at any point in z is a function of location in the field and the penetration depth

- The penetration depth of the evanescent wave is a function of the illumination wavelength.

- only 50nm to 100nm is typically useful illumination

Why is this useful for fluorescence microscopy?

- **The evanescent wave will typically only excite fluorophores within 50nm-80nm of the cover slip.**

- **Excitation of this small proportion of fluorophores in the thin optical section results in an extremely large increase in the S/N**

- **As a result of the increase in S/N very small signals, such as single molecule fluorescence, can be resolved above the noise floor**

TIRF is all about

SIGNAL to NOISE!

The Eyes Of Science.

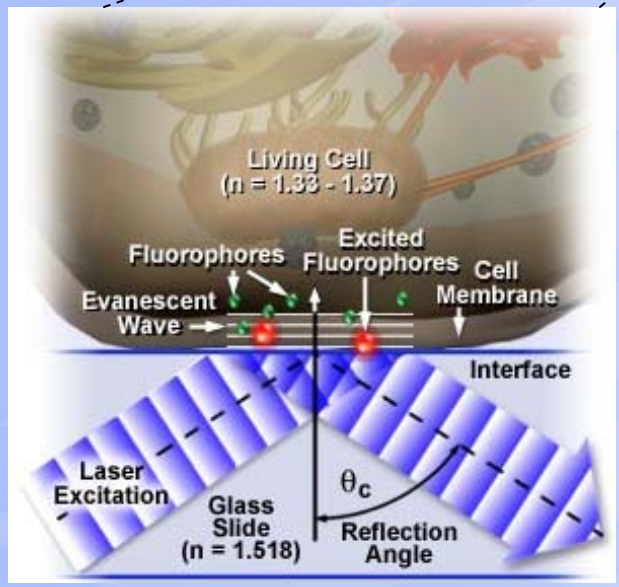
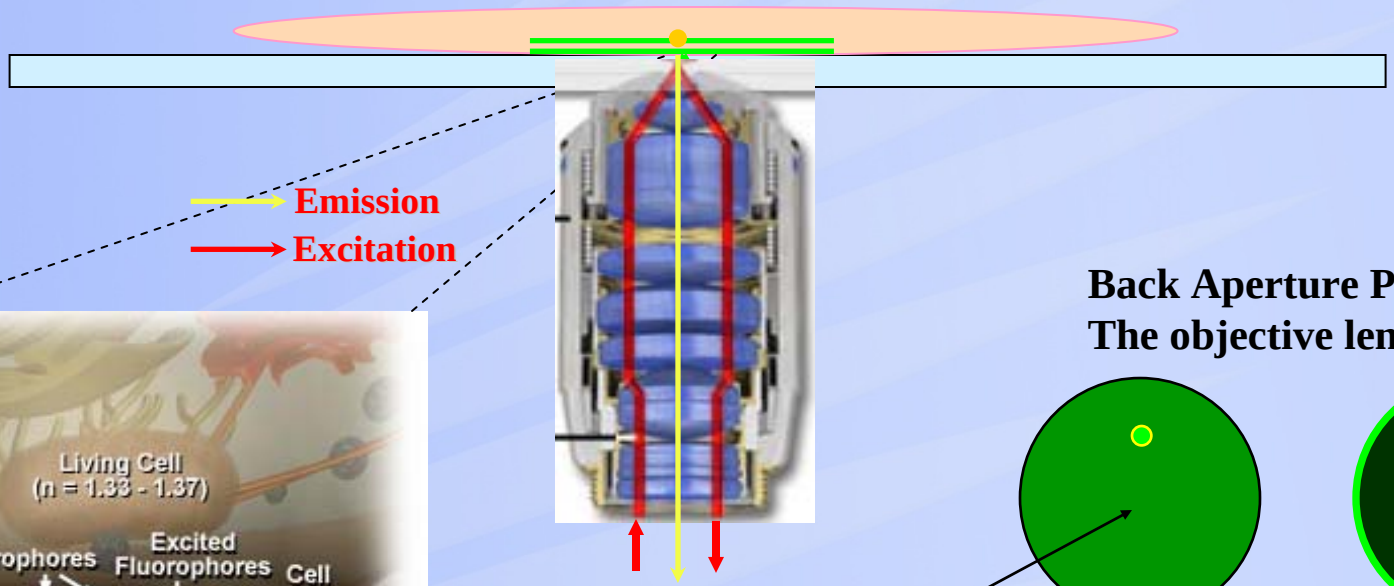
What are some of the applications of TIRF ?

- Endocytosis and Exocytosis
- Dynamics of membrane associated proteins
- Protein arrangement at membranes
- Focal adhesions
- Growth cone migration
- Receptor/Ligand interactions
- Biophysical studies of single molecule behavior

- ???? For you to figure out

Objective lens TIRF Method





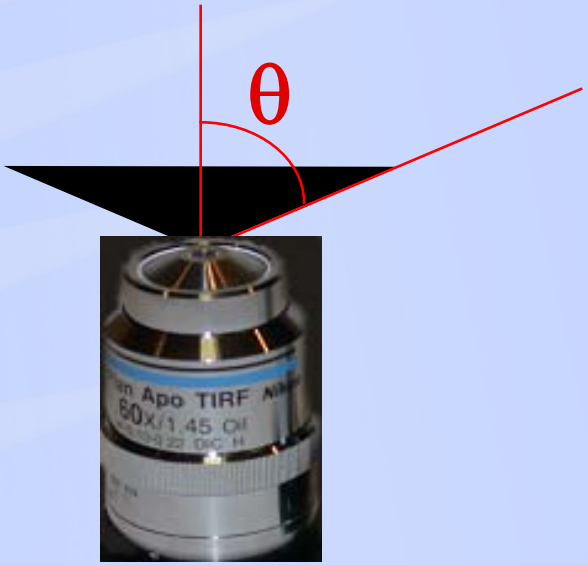
Back Aperture Plane of The objective lens

When a laser is focused at the back aperture plane of the objective in the low NA regions (left) it causes epi-illumination, however when the laser focus is moved to the high NA regions, beyond the n of the specimen., the light is totally internally reflected (right). Consequently, the aperture plane darkens and reveals an "Eclipse" of light at the perimeter.

High NA objective lenses are necessary for Total Internal Reflection, utilizing the lens method, so that light can come out of the lens at angles at or beyond the critical angle for TIR

$$NA = n \sin \theta$$

- **Numerical Aperture**
- **Mounting Media Refractive Index**
- **Angle of the Cone of illumination**



The Eyes of Science

Nikon
